Abstract

In Nigeria and most West African countries, the most common pest of animal products which also infest smoked-dry fish is *Dermestes maculatus* (fish weevil). The bio-insecticidal potentials of *Ageratum conyzoides* (goat weed) leaf powder and extract on fish weevils was evaluated with different doses of the plant materials (0.5 – 3.0 g and 50.0-100 mg ml⁻¹). Twenty unsexed adult weevils were exposed to these plant treatments which were all replicated thrice. The mortality rate was observed daily for 120 hours and 72 hours (h) with the use of the powder and extract respectively. The results of this study showed that mortality increased with the increase in gram (g) and the extract (mg ml⁻¹) concentration of *A. conyzoides*. Statistically, this indicates that the application of the *A. conyzoides* powder of different concentrations had a significant effect (P < 0.05; F = 13.69) on the mean percentage mortality of *D. maculatus* over a 120-hour period of exposure with a Median Lethal Concentration (LC₅₀) of 0.59 g , and Median Lethal Time (LT₅₀) of 22.80 h at 3.0 g. Comparatively, the extract application had no significant effect (P > 0.05) on the mean percentage mortality of *D. maculatus* over a seventy-two-hour exposure (P = 0.2573; F = 1.7422). The minimum LC₅₀ of the extract required to kill 50% of *D. maculatus* was determined as 36.86 mg ml⁻¹. The overall results showed that the extract was more toxic than the powder. The effectiveness of the phytochemical components of *A. conyzoides* against *D. maculatus*, as well as the local availability of the plant make it an attractive choice in pest-management practices. Therefore, dry fish traders are advised to use *A. conyzoides* for the protection and storage of smoked-dry fish against weevil infestations.

Keywords: Insecticidal, Toxicity, Mortality, Weevil, *Dermestes maculatus*, *Ageratum conyzoides*

1. Introduction

Smoked fish is one of the most widely distributed and cheapest animal protein product available in Nigeria. It is also an important source of food and income for many people, especially in the Southern part of Nigeria, where over 25% of the population depend on it as a rich source of protein, essential amino acids, vitamins and minerals (Azam et al., 2004; Aderolu and Akpabio, 2009 and Ito, 2017). In West Africa, particularly Nigeria; the total annual consumption of fish is 1.2 million tons (FAO, 2004 and FDF, 2005) of which 45% of the total fish catch are utilized as smoked fish (FAO, 2002). In Nigeria and most West African countries, the most common pest of animal products, which also infest smoked fish, is the hide weevil *Dermestes maculatus* (Degeer). A large-scale deterioration in quality, and 50% losses in quantity of dried fish, due to dermestid infestation, have been reported (Egwunyenga et al., 1998 and Odeyemi et al., 2000). Ito and Ighere (2017a) stated that during storage, transportation and marketing, smoked fish is readily attacked by several species of insects, notably *Dermestes maculatus*, *D. frischii*, *D. ater* and *Necrobia rufipes*. These weevils form aggregations of 1 – 13 weevils around food sources where individuals feed and mate (McNamara et al., 2008).

Problems of pest resistance/resurgence, residual/vertebrate toxicity, widespread environmental hazards, and the increasing costs of the application of synthetic insecticides have created a need for the utilization of effective, ecofriendly and biodegradable botanicals such as *Ageratum conyzoides* (goat weed), a promising botanical insecticide. The use of plant products in the control of insect pests is influenced by its availability, safety and effectiveness. *A. conyzoides* is a common weed found in several countries in tropical and sub-tropical regions, including Nigeria where its control is often difficult. The aqueous extracts of the whole plant have been used by Shabana et al., (1990) to cause a significant reduction of larvae emergence of root knot nematode, *Meloidogyne incognita*. Gbolade et al., (1999) also confirmed the

* Corresponding author. e-mail: ito.eddie@yahoo.com.
insecticidal properties of the volatile oil of *A. conyzoides* against *Callosobruchus chinensis* and *Tribolium castaneum* (Singh et al., 2014). The aqueous extracts of the leaves or whole plants have been used to treat colic, colds and fevers, diarrhea, rheumatism, spasms; they have been used also as a tonic (Negrelle et al., 1988; Oliveira et al., 1993). *A. conyzoides* contains monoterpenoids, diterpenoids, sesquiterpenoids and other compounds, including alkaloids, cumarins, flavonoids, chromenes (conyzorignum), benzofurans, sterols and terpenoids, which exhibit ovicidal, larvicidal, repellent, deterrent, antifeedant, and toxic effects in a wide range of insects. This study is aimed at evaluating the bioinsecticidal potentials of the leaf powder and extracts of goat weed, (*A. conyzoides*), on fish weevils (*Dermestes maculates*).

2. Materials and Methods

2.1. Preparation of Plant Powders

The leaves of *A. conyzoides* were dried under shade for several days to prevent breakdown and loss of phytochemical components. The dry leaves were ground by an electric blender and were sieved to obtain the powder which was stored in an air tight container.

2.2. Preparation of Crude Extracts

The extract of the *A. conyzoides* plant material was prepared by dissolving 50 g of the powder in 1000 mL of 95% ethanol, giving a concentration of 0.05 g/mL each. The extraction was done using the Soxhlet extractor. The process was repeated several times, and the supernatant of the plant extracts were decanted. A crude extract was obtained after the complete removal of the solvents with vacuum evaporation at temperature <40ºC to produce a thick liquid and syrupy material. From the main extract, 1.5 g, 2.25 g and 3 g were taken and dissolved in 30 mL of the solvent in a separate jar to produce a concentration of 50 mg/mL, 75 mg/mL and 100 mg/mL extract concentration which was used for the test.

2.3. Insect Culture and Maintenance

The *Dermestes maculates* weevils used in this study were obtained from infested catfish (*Clarias gariepinus*) bought locally from Abraka market in Delta State, Nigeria. The pest was cultured in the Department of Animal and Environment Biology Laboratory, Delta State University, Abraka. Heavily infested catfish were put in different plastic containers covered with muslin cloth, and held tightly in a place to prevent the entry and exit of the weevils. A new generation of *D. maculates* was obtained from the stock cultured by infesting clean uninfected catfish with adult *D. maculates*. The newly emerged insects were then collected and used for the study (Egwuyenga et al., 1998).

2.4. Toxicity Test of *A. conyzoides* Powders

The current study was carried out using four different doses (0.5, 1, 1.5, 2, 2.5 and 3 g) of *A. conyzoides* powders. Each dose was placed in a clean Petri dish and replicated three times. Ten grams of uninfested dry catfish (*C. gariepinus*) were put into the different Petri dishes containing the plant powder. This was done in the replicate of the different doses. Each Petri dish was shaken mechanically to ensure that the powder and dry catfish were thoroughly mixed. Twenty unsexed adult weevils were collected from the culture, and added to each treated catfish in the Petri dishes. The dishes were then covered to prevent the weevils from escaping. A control experiment consisting of ten grams of catfish and twenty weevils was also setup and replicated. The experimental set-up was observed for pest mortality over a period of 120 hours (5 days).

2.5. Toxicity Test of Crude Plant Extracts of *A. conyzoides*

This study was carried out using three different concentrations (50, 75, and 100 mg/mL) of the *A. conyzoides* leaf extract. Each concentration (50, 75 and 100 mg/mL) was used to treat the filter paper placed on a clean Petri dish, and was left for twenty-four hours to dry. These were replicated three times for each concentration. Ten grams of uninfected dry catfish (*C. gariepinus*) were put into the different Petri dishes containing the plant extract. This was done in the replicate of the different concentrations. Twenty unsexed adult weevils (*D. maculates*) were collected from the culture and added to each treated Petri dish. The dishes were then covered to prevent the escaping of the weevils. A control experiment consisting of ten grams of catfish and twenty weevils was also setup and replicated. The experimental set-up was observed for a period of seventy-two hours for pest mortality.

2.6. Statistical Analysis

The data collected were analyzed by finding the average number of dead *D. maculates* during the 120-hour exposure to the different concentrations, and then converting it to mortality percentage. The mean percentage mortality obtained was then subjected to a two-way ANOVA to determine the significant difference using SPSS 17, and the results were interpreted accordingly.

3. Results

The results of the assessment of the biopesticidal efficacy of *A. conyzoides* (goat weed) at different concentrations of powders and extracts against *D. maculates* (fish weevil) over a 120-hour period of exposure are presented in Tables 1 – 4.

3.1. Toxicity of *A. conyzoides* Powder on *D. maculates*

Table 1 shows that the daily (24 h interval) mean mortality of the unsexed catfish weevils under the effect of the *A. conyzoides* powder over a 24 – 120-hour exposure period gave a cumulative mean percentage mortality of 43.33, 76.67, 88.33, 96.67, 98.33 and 100% at 0.5, 1, 1.5, 2, 2.5, and 3 g concentrations respectively. This study also showed that mortality increased as the gram (g) concentration of the powder of *A. conyzoides* increased from 0.5 – 3.0 g. Statistically, this indicated that the application of the *A. conyzoides* powder with different concentrations had a significant (*P* < 0.05; *F* = 13.69) effect on the mean percentage mortality of *D. maculates* over a 120-hour period of exposure. The data presented in Table 1 revealed also that the *A. conyzoides* powder at its peak concentration (3.0 g) gave the highest mortality (100%) of fish weevils. The first twenty-four hours of application of the plant powder recorded the highest weevil mortality with all the concentration of *A.
conyzoides (Table 1). However, no mortality was observed in the negative control (triplicates without plant treatment).

The results of the probit analysis percentage for the median lethal concentration (LC50) on the mortality of *D. maculatus* is presented in Figure 1. The minimum concentration required to kill 50% of the fish weevils was determined to be a concentration of 0.59 g (Table 1).

### 3.1.1. Median Lethal Time LT50 of *A. conyzoides* Powder

The respective regression equation, R2 and LT50 values caused by the plant powders at different concentrations are presented in Table 2. The minimum time required to kill 50% of *D. maculatus* at 0.5 – 3.0 g of *A. conyzoides* was determined (Figures 2 – 7). The LT50 value for gram concentration after the treatment indicated that 3.0 g was the most toxic at the minimum time giving an LT50 of 22.80 h (Table 2). 0.5 g was the least effective dose causing a mortality rate of 50% of *D. maculatus* over an exposure time of 115.2 hours.

**Table 1.** Mean percentage mortality (Mean ± S.E) of *D. maculatus* exposed to *A. conyzoides* leaf dust in 120 hours.

**Figure 1.** Percentage probit kill of *D. maculatus* exposed to *A. conyzoides* gram concentration at

**Figure 2.** Time-mortality (LT50) response of *D. maculatus* exposed to 0.5 g of *A. conyzoides* dust.
3.2. Toxicity of A. conyzoides Extract on D. maculatus

The mortality caused by A. conyzoides also showed a similar mortality trend similar to the powder. Here, mortality of D. maculatus increased with increasing the concentration (mg-mL) of the extract used in the test; hence the mortality was concentration-dependent. The extract of A. conyzoides at 75.0 and 100.0 mg-mL per ten grams of smoked catfish exhibited the highest cumulative mean mortality of 93.34 % and 100.0% respectively (Table 3). ANOVA showed that the application of A. conyzoides extract at different concentrations had no significant effect (P > 0.05) on the mean percentage mortality of D. maculatus over a seventy-two-hour period of exposure (P = 0.2573; F = 1.7422). The results for the probit analysis percentage for median lethal concentration (LC 50) on the mortality of D. maculatus is presented in Figure 8. The minimum concentration required to kill 50% of the fish weevils was determined to be an extract concentration of 36.86 mg-mL (Table 3).

3.2.1. Median Lethal Time LT50 of the A. conyzoides Extract

The regression equation, (R² and LT50) values caused by the leaf extract of the plant at different concentrations are presented in Table 4. The minimum time required to kill 50% of D. maculatus at 50.0 – 100.0 mg-mL of A. conyzoides was also determined and presented in Figures 9 – 11). The LT50 value for all the extract concentrations after the treatment indicated that 100.0 mg-mL was the most toxic with the minimum time giving an LT50 of 15.40 h (Table 4). The least effective dose was 50.0 mg-mL, causing 50% mortality of D. maculatus after 26.48 hours of exposure.

### 4. Discussion

The current study showed that the *A. conyzoides* powder treatment was toxic to *D. maculatus*, and the application of the powder at different concentrations had a significant effect (*P* < 0.05) on the mean percentage mortality of the weevils over a 120-hour period of exposure. A high mortality rate of 100.0% of the weevils was recorded at 3.0 g of the *A. conyzoides* powder per ten grams of the substrate (dry smoked catfish). This finding is in agreement with Singh et al., (2014) who reported a 100.0% mortality rate of *T. castaneum* using *A. conyzoides*. Similarly, Akinwumi (2011) also documented a 100.0% rate killing *D. maculatus* with ten grams of powder per 100.0 g of fish using *Dennettia tripetala, Eugenia aromatic, Piper guineense*, and *Monodora myristica*. The current study also revealed that the minimum concentration required to kill 50% of the fish weevils was 0.59 g of the plant/10.0 g of smoked-dried fish (Table 1).

In the present study, there was no significant difference (*P*>0.05) in the percentage of mortality of *D. maculatus* using *A. conyzoides* extracts as shown by the statistical analysis. In all treatments, mortality was relatively more at higher doses (2.5 g and 3.0 g), and more with the extract analysis. In all treatments, mortality was relatively more at (95% CI) 0.05) in the percentage of mortality of *D. maculatus* weevils was 0.59 g of the plant/10.0 g of smoked-dried fish. Vyas and Mulchandani (1980) reported the insect, rather than being the direct cause to insect activity that may affect the growth and development of the insect, rather than being the direct cause to insect activity that may affect the growth and development of the fish. Singh et al. (2014) reported that the leaf powder of *A. conyzoides* has less bioactive substances than the extract. The cause of the high mortality of *D. maculatus* adults within three to five DAT could be due to conyzgorum substances in *A. conyzoides* which act as an antifeedant and a stomach poison. There is a possibility that the active component, conyzgorum, whose synergetic effects of precocenes I and II was at the highest concentration in the extract resulting in rapid mortality of adult *D. maculatus*.

### 5. Conclusion

The use of indigenous plant-based products by individuals and communities can provide prophylactic measures for the protection against various insect pest infestations. Therefore, smoked-fish traders are advised to use the *A. conyzoides* plant, commonly called “shell leaf”, in Nigeria, for the better protection and storage of their products, because of its effectiveness, less hazards, availability and easy accessibility, and also for its medicinal functions. The ethanolic extract of *A. conyzoides* is a better botanical insecticide; however, further studies need to be conducted to ascertain which phytochemical is the active ingredient responsible for the *D. maculatus* mortality.

### Acknowledgment

We would like to thank the Administration at Delta State University in Abraka, particularly Dr. J.E.G Ake, of the Department of Animal and Environmental Biology for his constructive criticism. We also thank the Tropical Disease Research (TDR) Unit and the Center for Research in Environmental Resources Management (CREMA) for providing facilities, research grants, and enabling environments for this research.
